

A Greenhouse Gas Budget for Mexico During 2000–2019

Murray-Tortarolo, G, et al. (2024). A Greenhouse Gas Budget for Mexico During 2000–2019. *JGR Biogeosciences*, 129(1), e2023JG007667. <https://doi.org/10.1029/2023JG007667>

Science Question

- What is the greenhouse gas budget for Mexico over the past two decades (2000-2019)?
- What are the emissions and removals of CO₂, CH₄ and N₂O by natural and anthropogenic sectors?
- Where are main discrepancies and uncertainties in datasets and integration?
- The work is carried out as part of the REgional Carbon Cycle and Processes study (RECCAP2).

Analysis

- Data from the Mexico National Greenhouse Gas Inventory (NGHGI), land-surface models, and atmospheric inversions were combined to estimate greenhouse gas emissions and removals.
- The data included estimates for natural sources (i.e., terrestrial ecosystems and wetlands) and anthropogenic sectors (fossil fuels, agriculture, waste, land-use and land cover change).

Results/Significance

- Mexico is a source of GHG emissions, ranging from 695-910 TgCO₂-eq yr⁻¹.
- Seventy percent of emissions are attributed to CO₂, 23% to CH₄ and 5% to N₂O.
- There is good agreement across anthropogenic sectors and less agreement for the land carbon sink.
- NGHGI estimates were much larger removals than other modeled estimates.
- Lateral fluxes and outgassing processes from aquatic systems remain problematic for double counting and for helping reconcile bottom-up and top-down budgets
